In support of research being conducted by the Properties and Phenomena Branch, Solid State Stences Laboratory, Air Force Cambridge Research Laboratory, ManLabs, Inc. is conducting a service effort that is directed toward the characterization of specified physical, chemical and structural properties of various materials. Experimental methods include chemical analysis, reflection electron microscopy and diffraction, X-Ray diffraction and flourescence analysis, light microscopy and electron microprobe analysis, in addition to the determination of specific properties, such as density, hardness and thermal conductivity. Special services, such as crystal orientation, cutting, grinding and polishing are also being performed. Specific materials submitted for characterization include spinel, lithium germanate, silicon germanium, silicon carbide, quartz, ruby, gallium arsenide, yttrium-iron garnet, yttrium-aluminum garnet, lithium niobate, bismuth germanate, subidium iodate, lithium tantalate, sodium chloride, calcium fluoride, zirconium, cadmium teluride, potassium chloride, cebalt silicide, \(\beta\)-silicon carbide, gallium phosphide, Nd-glass, and rubiduim bromide. In addition,' a variety of specimens have been submitted for specific studies such as phase identification, crystallinity and chemical analysis.

FOREWORD

This report was prepared by ManLabs, Inc., 21 Erie Street Cambridge, Massachusetts, under Air Force Contract No. F19628-70-C-0140. The work was administered by the Office of Aerospace Research, Air Force Cambridge Research Laboratories, United States Air Force, Bedford, Massachusetts, with Mr. Norman Pickering providing technical liaison.

ManLabs personnel that have participated in this program are Dr. S. Andrew Kulin, Dr. Edward V. Clougherty, Konstantin Kreder Harvey Nesor, Edward P. Warekois, Joseph Davis, Kathleen Meany, Henry Plimpton.

This is a technical report and describes studies which were initiated 1 December 1970 and were concluded 1 December 1971.

ABSTRACT

In support of research being conducted by the Properties and Phenomena Branch, Solid State Sciences Laboratory, Air Force Cambridge Research Laboratory, ManLabs, Inc. is conducting a service effort that is directed toward the characterization of specified physical, chemical and structural properties of various materials. Experimental methods include chemical analysis, reflection electron microscopy and diffraction, X-Ray diffraction and flourescence analysis, light microscopy and electron microprobe analysis, in addition to the determination of specific properties, such as density, hardness and thermal conductivity. Special services, such as crystal orientation, cutting, grinding and polishing are also being performed. Specific materials submitted for characterization include spinel, lithium germanate, silicon germanium, silicon carbide, quartz, ruby, gallium arsenide, yttrium-iron garnet, yttrium-aluminum garnet. lithium niobate, bismuth germanate, rubidium iodate, lithium tantalate, sodium chloride, calcium fluoride, zirconium, cadmium teluride, potassium chloride, cobalt silicide, β -silicon carbide, gallium phosphide, Nd-glass, and rubidium bromide. In addition, a variety of specimens have been submitted for specific studies such as phase identification, crystallinity and chemical analysis.

I. INTRODUCTION

ManLabs, Inc. is conducting a service and research effort in support of work carried out by the Properties and Phenomena Branch, Solid State Sciences Laboratory, AFCRL. This effort is directed to the characterization of the physical properties of electronic materials, devices and thin films and to the fabrication of various electro-optical experimental components. The experimental methods which are employed have been described in "Physical Characterization of Electronic Materials, Devices and Thin Films", by S. Andrew Kulin and Konstantin Kreder, Scientific Report Nc. 1. AFCRL Contract No. F19628-70-C-0140, January 1, 1971.

Requests for services are individually submitted and experimental results are conveyed in letter reports. Liaison personnel are Jane Bruce and Norman Pickering, AFCRL and Dr. S. Andrew Kulin and K. Kreder, ManLabs, Inc.

Personnel contributing to the materials characterization studies and services during this reporting period include Dr. S. A. Kulin, Harvey Nesor, Konstantin Kreder, Joseph Davis, E.P. Warekois, K. Meaney and Harry Tushman.

II. EXPERIMENTAL METHODS

The following experimental methods and procedures have been employed in the course of the program.

A. X-ray Diffraction

Back reflection X-ray patterns have been utilized to determine the crystallinity of specimens. Polycrystalline materials yield ring (pin hole) patterns which can be used for qualitative measures of grain size, lattice parameter and preferred orientation. Single crystal materials yield spot (Laue) patterns which are utilized to confirm crystallinity, to provide crystal orientation and to give a qualitative estimate of crystal strain and perfection. The lattice perfection is based upon observed spot distortion, diffuseness or frag mentation. Single crystal orientation is carried out by conventional back-reflection Laue methods. The specimen holder is transferred from the X-ray unit directly to the grinding machine where specific specimen configurations are prepared by appropriate cutting and grinding. When required, the specimen faces are polished by hand lapping with diamond, alumina, or other special abrasive materials.

Quantitative crystal perfection measurements have been carried out by means of a double crystal spectrometer. In operation, an analysing crystal of high perfection is used to produce a monochromatic, parallel X-ray beam. This radiation impinges upon the second (specimen) crystal, which is slowly rotated through an angle w about a rocking axis which is included in the surface of the specimen and is perpendicular to the X-ray plane. The resulting rocking curve (X-ray intensity versus w) that is obtained from reflection planes parallel to the specimen surface has an

angular breadth at half maximum intensity which is directly related to small angle tilt boundaries and dislocation-strain distributions within the specimen. After correcting for geometrical and natural (Darwin-Prins) broadening, the half breadth values can be utilized in calculating dislocation densities.

B. Crystal Cutting and Polishing

The experimental procedures used to fabricate crystals of various sizes and shapes were generally as follows: The boule was mounted onto a brass block with "quartz cement" and was X-ray oriented to the specific crystallographic plane. The required shapes were then cut and ground with diamond wheels using a Sanford Surface Grinder and machine polished or lapped using a Crane Lapmaster 12. After rough polishing, the final orientation of the crystal was checked by taking an X-ray Laue pattern and in certain cases, by use of a horizontal diffractometer.

In order to obtain crystals of good quality, i.e. smooth surface and completely without flaws, the machine lapping operation was followed by hand lapping on a precision ground glass covered with suitable abrasive and moving with a sweeping motion over the glass surface preferably in the form of figure eights. Surface flatness of about one wavelength of sodium light and surface parallelism of about 10 sec. of arc or better was routinely maintained during the fabrication of the crystallographically oriented plates of quartz, linobates, germanates and other crystals.

C. Electron Diffraction

The crystallinity and orientation of several thin film deposits have been examined by reflection electron diffraction in which the specimen is placed almost parallel to an electron beam. Electrons diffract from surface asperities and are recorded on a film placed below the specimen.

Amorphous materials yield very broad, diffuse ring or halo patterns, polycrystalline materials yield concentric ring patterns and single crystal materials yield spot patterns. The ring patterns can be utilized to determine interplanar spacings of the reflecting planes, allowing specimen indentification. Single crystal spot patterns can be analyzed to determine both the structural identification and orientation of the specimen.

Particular orientations are achieved by rotations about two orthogonal axes normal to the electron beam and by a lateral translation. The camera constant (i.e., the relation between ring radius or spot distance from film center to interplaner spacing) is determined by means of a known standard. This constant is strongly dependent on electron beam voltage, but is rather insensitive to other microscope adjustments. All examinations reported herein have been carried out on a Hitachi HU-11 Electron Microscope operated at 100ky.

D. Chemical Analyses

A fully equipped analytical laboratory was available for wet chemical, emission spectrographic and spectrochemical analyses.

E. Hardness

Specimens were mounted in epoxy and were polished to about a 1 micron surface finish to provide a uniform flat surface. Hardness measurements were made on a Leitz Durimet Microhardness Tester utilizing either Knoop or Vickers pyramid indentors. Hardness values are reported in kg/mm².

III. EXPERIMENTAL RESULTS

A listing of the various services provided during the past quarter is presented in Table 1. The experimental findings are summarized below.

A. X-Ray Procedures - Crystal Orientation

The orientation of a number of crystals was determined using back-reflection X-ray Laue techniques. Laue patterns were also utilized to indicate crystal perfection. When a precision crystaliographic orientation was required, the crystal was first X-ray oriented within $\pm 1/2^{\circ}$ with respect to a given crystallographic direction using a Laue Back Reflection Cambra after which a set of reference surfaces was optimized using a Philips Horizontal X-Ray Diffractometer with independent movement of the 9 and 20 arms. The precision of crystal orientation by this method is known to be at least ± 5 minutes of arc. The results of the crystal orientation work is summarized in Table 2.

B. Crystal Cutting and Polishing

A number of quartz, YIG, YAG, potassium chloride, sodium chloride, gallium arsenide, gallium phosphide, bismuth germanate, lithium niobate and lithium tantalate crystals have been X-ray oriented, cut and polished according to stated size specifications and specimen orientations. The experimental procedures were generally as follows: the crystals were mounted onto steel blocks with "quartz cement" and were oriented to the specified crystal plane by back reflection X-ray Laue methods. The required pieces were fabricated by cutting and grinding with diamond wheels and were then polished to obtain the desired surface finish. The final orientations were checked by X-ray Laue patterns and, in certain cases, by use of a horizontal diffractometer designed for single crystal orientation work

A number of services requests during this reporting period required crystals to be polished having surface finishes at least $\lambda/10$ in flatness.

The various crystals and specimen dimensions are given in Table 3.

C. Fabrication of Modified Cylinders

During this reporting period work has progressed on the fabrication of modified cylinders out of quartz, LiNbO₃. amd BGO. Techniques have been applied which permit highly precise grinding of the cylinder outer diameters i.e. T.I.R. of only a few millionths of an inch. Special devices have been designed and constructed to polish the outer diameters on a centerless principle. Excellent polished surface finishes have been obtained.

The fabrication of these modified cylinders has necessitated the construction of X-ray orientation devices. The polished cylinders were protected with a plastic coating during X-ray orientation, grinding, and polishing of the flat surfaces. Attention is being given to methods of handling during microscopic inspection and ultimately during delivery of these precise parts. This part of the program is nearing completion.

D. Election Diffraction

A number of thin film deposits of β -SiC have been submitted for electron diffraction analysis. These epitaxially grown films were produced on various substrates and under a variety of experimental conditions at AFCRL. The samples were analyzed by electron diffraction to determine the degree of crystallinity and for purposes of phase identification. Some detailes on the methods follow below.

The specimen surface is placed almost parallel to the electron beam in reflection electron diffraction. The electrons diffract from surface asperities and are recorded on a film placed below the specimen. Amorphous materials yield concentric ring patterns and single crystal materials yield spot patterns. The ring patterns can be utilized to determine interplanar spacings of the reflecting planes, allowing specimen identification. In cases of large

crystallites (>10 microns), the rings tend to be spotty; for very small crystallites (<0.1 microns) or strained materials, the rings become diffuse.

Single crystal spot patterns can be utilized to determine the structural identification and orientation of the specimen. Particular orientations are achieved by rotations about two orthogonal axes normal to the electron beam and by a lateral translation. The camera constant (i.e., the relation between ring radius or spot distance from film center to interplaner spacing) is determined by means of a known standard. This constant is strongly dependent on electron beam voltage, but is rather insensitive to other microscope adjustments. All analyses reported herein have been carried out on a Hitachi HU-11 Electron Microscope operated at 100kv.

E. Chemical Analyses

Wet chemical and spec..:ochemical analyses were carried out on several specimens with the result shown in Table 4 below:

TABLE 4

CHEMICAL ANALYSES

Job No.	Spec. No.	Chemistry	Results
04106	RB-1	RbIO ₃	$I = 62.5^{W}/o$ $Rb = 13.7^{W}/o$ $HIO = 57.4^{W}/o$
04159	JS-Zr	Zirconium	$C = 1.85^{W}/o$ $N = 0.079^{W}/o$ $H = 0.026^{W}/o$ S = none $Si = 0.014^{W}/o$ $Zr = 92.04^{W}/o$
04491		Cadmium Telluride	Cd = $43.9^{W}/o$ Te = $56.1^{W}/o$

F. Microhardness Measurements

Microhardness meausrements were performed utilizing a Leitz Microhardness Tester with Vickers or Knoop indentor and a 15gm load. An average hardness value based on five readings was obtained for various salt crystals and the results are summarized below:

TABLE 5
MICROHARDNESS MEASUREMENTS
